System notes / current limits

Review copy, 21 October 2026. These are implementation notes for the next increment. Local routes are available for inspection; no production sample is attached.

Read the storefront path carefully: product and quantity create a pending order directly. The cart in the sketch is future work. A button alone does not prove an endpoint exists.

The proposed handoff

Order Platform and Inventory keep different records. The stock lock protects a local decrement. We have not chosen duplicate delivery or cancellation compensation.

The intended asynchronous path starts when Submit Order publishes Order Submitted. Inventory should react by reserving stock and publish Stock Reserved; Orders should react by sending the confirmation. In the current build the submit handler is commented out and neither event consumer is running. Manual status changes do not publish an order-confirmed event. A successful inventory HTTP call alone proves none of this integration.

Budgets needing evidence

21 October service review. Orders proposes 99.9% successful order API journeys over a rolling 30 days, with a 0.1% error budget and a page to the on-call engineer on breach. The sample must include submission and read-back. This threshold has not received joint sign-off.

Orders submission has a proposed p95 latency below 500 ms over a rolling 30-day window. This is a service budget, not the separate two-second end-to-end business goal. No running submit handler means no production latency proof yet.

The shop should be open 24/7 with no maintenance window. The 99.9% calendar-month availability figure is a planning assumption only; the product lead has not agreed that percentage.

The product lead agreed on 4 October that 99% of shopper interactions must answer within one second. Measuring those interactions is still open work; the commitment is not a measured result.
